

This paper investigates the mechanical response of Double GUs (DGUs) simply supported on two opposite sides under concentrated and linear loads, with different geometries.

Double glass components have become a cornerstone in modern solar panel design, offering enhanced durability and efficiency. However, their production presents unique challenges that manufacturers ...

The function of the breathing tube and capillary tube is to continuously adjust the difference between the pressure in the air layer of the double glazed units and the external atmospheric pressure as the ...

An insulating glass unit is sealed at the particular pressure on the day of manufacture. As the pressure outside the insulating glass unit changes, an imbalance occurs between the internal cavity pressure ...

The properties of glasses, from chemical to thermal and mechanical, depend on the network structure. This includes how it responds not only to changes in glass composition but also ...

Insulating glass units (IGUs) are building components that show particular structural behavior. A typical IGU comprises two or more glass panes with a sealed gap filled with a low ...

Insulating glass units (IGU) are classic constructions used to fill standard windows and glass facades. Their task is primarily to reduce heat loss in buildings. A unit consists of two or more glass panes ...

A simple method was devised for calculating the pressure differences that occur on sealed double glazing units due to the combined effect of changes in temperature and barometric ...

Which brings us to our final installment in the series-- Glass under pressure. The articles highlighted this month discuss in greater detail the effects of pressurized glass forming and use ...

pressure-transmitting medium is employed to give hydrostatic conditions. More generally, the force acting on a surface will have components that are both perpendicular and parallel
